(54) **Strip casting apparatus**

(57) A nozzle for delivering molten metal to a casting pool of a twin roll strip caster is formed in two halves and comprises an upwardly opening trough (61) to receive falling supply streams of molten metal and outlet openings (64) at the bottom of the trough. Nozzle end formations (87) define reservoirs (88) to receive separate sup-

ply streams of molten metal and flow passages (95) to direct metal from the reservoirs across pool confining end closures of the caster. Each reservoir (88) is separated from trough (61) by an upstanding wall (70) which functions as a weir for metal in the reservoir such that metal can flow over it into the trough when the reservoir is full.

Description

BACKGROUND OF THE INVENTION

This invention relates to the casting of metal strip. It has particular but not exclusive application to the casting of ferrous metal strip.

It is known to cast metal strip by continuous casting in a twin roll caster. Molten metal is introduced between a pair of contra-rotated horizontal casting rolls which are cooled so that metal shells solidify on the moving roll surfaces and are brought together at the nip between them to produce a solidified strip product delivered downwardly from the nip between the rolls. The term "nip" is used herein to refer to the general region at which the rolls are closest together. The molten metal may be poured from a ladle into a smaller vessel from which it flows through a metal delivery nozzle located above the nip so as to direct it into the nip between the rolls, so forming a casting pool of molten metal supported on the casting surfaces of the rolls immediately above the nip. This casting pool may be confined between side plates or dams held in sliding engagement with the ends of the rolls.

Although twin roll casting has been applied with some success to non-ferrous metals which solidify rapidly on cooling, there have been problems in applying the technique to the casting of ferrous metals which have high solidification temperatures and tend to produce defects caused by uneven solidification at the chilled casting surfaces of the rolls. Much attention has therefore been given to the design of metal delivery nozzles aimed at producing a smooth even flow of metal to and within the casting pool. United States Patents 5,178,205 and 5,238,050 both disclose arrangements in which the delivery nozzle extends below the surface of the casting pool and incorporates means to reduce the kinetic energy of the molten metal flowing downwardly through the nozzle to a slot outlet at the submerged bottom end of the nozzle. In the arrangement disclosed in US Specification 5,178,205 the kinetic energy is reduced by a flow diffuser having a multiplicity of flow passages and a baffle located above the diffuser. Below the diffuser the molten metal moves slowly and evenly out through the outlet slot into the casting pool with minimum disturbance. In the arrangement disclosed in US Specification 5,238,050 streams of molten metal are allowed to fall so as to impinge on a sloping side wall surface of the nozzle at an acute angle of impingement so that the metal adheres to the side wall surface to form a flowing sheet which is directed into an outlet flow passage. Again the aim is to produce a slowly moving even flow from the bottom of the delivery nozzle so as to produce minimum disruption of the casting pool.

Japanese Patent Publication 5-70537 of Nippon Steel Corporation also discloses a delivery nozzle aimed at producing a slow moving even flow of metal into the casting pool. The nozzle is fitted with a porous

baffle/diffuser to remove kinetic energy from the downwardly flowing molten metal which then flows into the casting pool through a series of apertures in the side walls of the nozzle. The apertures are angled in such a way as to direct the in-flowing metal along the casting surfaces of the rolls longitudinally of the nip. More specifically, the apertures on one side of the nozzle direct the in-flowing metal longitudinally of the nip in one direction and the apertures on the other side direct the in-flowing metal in the other longitudinal direction with the intention of creating a smooth even flow along the casting surfaces with minimum disturbance of the pool surface.

After an extensive testing program we have determined that a major cause of defects is premature solidification of molten metal in the regions where the pool surface meets the casting surfaces of the rolls, generally known as the "meniscus" or "meniscus regions" of the pool. The molten metal in each of these regions flows towards the adjacent casting surface and if solidification occurs before the metal has made uniform contact with the roll surface it tends to produce irregular initial heat transfer between the roll and the shell with the resultant formation of surface defects, such as depressions, ripple marks, cold shuts or cracks.

Previous attempts to produce a very even flow of molten metal into the pool have to some extent exacerbated the problem of premature solidification by directing the incoming metal away from the regions at which the metal first solidifies to form the shell surfaces which eventually become the outer surfaces of the resulting strip. Accordingly, the temperature of the metal in the surface region of the casting pool between the rolls is significantly lower than that of the incoming metal. If the temperature of the molten metal at the pool surface in the region of the meniscus becomes too low then cracks and "meniscus marks" (marks on the strip caused by the meniscus freezing while the pool level is uneven) are very likely to occur. One way of dealing with this problem has been to employ a high level of superheat in the incoming metal so that it can cool within the casting pool without reaching solidification temperatures before it reaches the casting surfaces of the rolls.

In recent times it has been recognised that the problem of premature solidification can be addressed more efficiently by taking steps to ensure that the incoming molten metal is delivered relatively quickly by the nozzle directly into the meniscus regions of the casting pool. This minimises the tendency for premature freezing of the metal before it contacts the casting roll surfaces. It has been found that this is a far more effective way to avoid surface defects than to provide absolutely steady flow in the pool and that a certain degree of fluctuation in the pool surface can be tolerated since the metal does not solidify until it contacts the roll surface. Examples of this approach are to be seen in Japanese Patent Publication 64-5650 of Nippon Steel Corporation and our Australian Patent Application 60773/96.

Although the direction of molten metal from the delivery nozzle directly to the meniscus regions of the casting pool allows casting with molten metal supplied with relatively low level of superheat without the formation of surface cracks, problems can arise due to the formation of pieces of solid metal known as "skulls" in the vicinity of the pool confining side plates or dams. These problems are exacerbated as the superheat of the incoming molten metal is reduced. The rate of heat loss from the melt pool is greatest near the side dams due primarily to additional conductive heat transfer through the side dams to the roll ends. This high rate of local heat loss is reflected in the tendency to form "skulls" of solid metal in this region which can grow to a considerable size and fall between the rolls causing defects in the strip. Because the net rate of heat loss is higher near the side dams the rate of heat input to these regions must be increased if skulls are to be prevented. There have been previous proposals to provide an increased flow of metal to these "triple point" regions (ie. where the side dams and casting rolls meet in the meniscus regions of the casting pool) by providing flow passages in the end of the core nozzle to direct separate flows of metal to the triple point regions. Examples of such proposals may be seen in United States Patent 4,694,887 and in United States Patent 5,221,511.

Although triple point pouring has been operated successfully to reduce the formation of skulls in the triple point regions of the pool it is generally not been possible completely to eliminate the problem because the generation of defects is remarkably sensitive to even minor variations in the flow of molten metal through the triple point flow passages. Excessive flow produces bulging in the edges of the strip and too little flow results in rapid formation of skulls and "snake egg" defects in the strip. The present invention addresses these problems by providing a nozzle with triple point pouring end formations designed to provide accurate control of the flow to the triple point regions of the pool.

SUMMARY OF THE INVENTION

According to the invention there is provided apparatus for casting metal strip, comprising a pair of parallel casting rolls forming a nip between them, an elongate metal delivery nozzle disposed above and extending along the nip between the casting rolls for delivery of molten metal into the nip whereby to form a casting pool supported above the nip, a distributor disposed above the delivery nozzle for supply of molten metal to the delivery nozzle in discrete streams, and a pair of pool confinement plates at the ends of the nip, wherein the metal delivery nozzle comprises an upwardly opening elongate trough extending longitudinally of the nip to receive discrete streams of molten metal from the distributor and trough outlet means to deliver molten metal from the trough into the casting pool, the nozzle has outer end formations defining reservoirs for molten metal at the

two ends of the nozzle which each receive discrete streams of metal from the distributor and flow passages extending from the reservoirs to direct molten metal from the reservoirs in streams directed downwardly across the pool confining end closures, and each of said reservoirs is separated from the nozzle trough by separator means establishing a maximum depth of accumulated molten metal in the reservoir beyond which molten metal can overflow from the reservoir into the nozzle trough.

Preferably, the separator means is in the form of an upstanding wall constituting an outer end wall of the trough and an inner end wall of the reservoir.

Preferably further said upstanding wall functions as a weir for molten metal in the reservoir such that metal can flow over it into the trough when the reservoir is full.

Preferably, each reservoir is in the form of an open topped dish which is shallow relative to the trough and is elevated above the floor of the trough.

Preferably further the undersides of the nozzle end formations are raised above the bottom end of the nozzle so as in use of the apparatus to be raised clear of the casting pool.

Preferably further the undersides of the nozzle end formations slope upwardly and outwardly of the nozzle ends.

Preferably too, the nozzle receives a plurality of discrete streams of molten metal from the distributor throughout the length of the nozzle.

Preferably further, the volume of the discrete streams received to the outer end formations is larger than the individual discrete streams received by said upwardly opening trough.

The invention further provides a refractory nozzle for delivery of molten metal to a casting pool of a twin roll caster, said nozzle comprising an elongate open topped trough to receive molten metal and trough outlet means for delivery of molten metal from the trough to the casting pool, which nozzle is provided with end formations defining reservoirs to receive molten metal at the two ends of the nozzle and flow passages extending from the reservoirs to direct molten metal from the reservoirs in streams directed downwardly from the nozzle end formations, wherein each of said reservoirs is separated from the nozzle trough by separator means establishing a maximum depth of accumulated molten metal in the reservoir beyond which molten metal can overflow from the reservoir into the nozzle trough.

BRIEF DESCRIPTION OF THE DRAWINGS

In order that the invention may be more fully explained one particular method and apparatus will be described in some detail with reference to the accompanying drawings in which:

Figure 1 illustrates a twin-roll continuous strip caster constructed and operating in accordance with the

present invention;

Figure 2 is a vertical cross-section through important components of the caster illustrated in Figure 1 including a metal delivery nozzle constructed in accordance with the invention;

Figure 3 is a further vertical cross-section through important components of the caster taken transverse to the section of Figure 2;

Figure 4 is an enlarged transverse cross-section through the metal delivery nozzle and adjacent parts of the casting rolls;

Figure 5 is a side elevation of a one half segment of the metal delivery nozzle;

Figure 6 is a plan view of the nozzle segment shown in Figure 5;

Figure 7 is a longitudinal cross-section through the delivery nozzle segment;

Figure 8 is a perspective view of the delivery nozzle segment;

Figure 9 is an inverted perspective view of the nozzle segment;

Figure 10 is a transverse cross-section through the delivery nozzle segment on the line 10-10 in Figure 5;

Figure 11 is a cross-section on the line 11-11 in Figure 7; and

Figure 12 is a cross-section on the line 12-12 in Figure 7.

DESCRIPTION OF THE PREFERRED EMBODIMENT

The illustrated caster comprises a main machine frame 11 which stands up from the factory floor 12. Frame 11 supports a casting roll carriage 13 which is horizontally movable between an assembly station 14 and a casting station 15. Carriage 13 carries a pair of parallel casting rolls 16 to which molten metal is supplied during a casting operation from a ladle 17 via a distributor 18 and delivery nozzle 19. Casting rolls 16 are water cooled so that shells solidify on the moving roll surfaces and are brought together at the nip between them to produce a solidified strip product 20 at the nip outlet. This product is fed to a standard coiler 21 and may subsequently be transferred to a second coiler 22. A receptacle 23 is mounted on the machine frame adjacent the casting station and molten metal can be diverted into this receptacle via an overflow spout 24 on the distributor.

Roll carriage 13 comprises a carriage frame 31 mounted by wheels 32 on rails 33 extending along part of the main machine frame 11 whereby roll carriage 13 as a whole is mounted for movement along the rails 33. Carriage frame 31 carries a pair of roll cradles 34 in which the rolls 16 are rotatably mounted. Carriage 13 is movable along the rails 33 by actuation of a double acting hydraulic piston and cylinder unit 39, connected between a drive bracket 40 on the roll carriage and the main machine frame so as to be actuable to move the

roll carriage between the assembly station 14 and casting station 15 and visa versa.

Casting rolls 16 are contra rotated through drive shafts 41 from an electric motor and transmission mounted on carriage frame 31. Rolls 16 have copper peripheral walls formed with a series of longitudinally extending and circumferentially spaced water cooling passages supplied with cooling water through the roll ends from water supply ducts in the roll drive shafts 41 which are connected to water supply hoses 42 through rotary glands 43. The rolls may typically be about 500 mm diameter and up to 2 m long in order to produce up to 2 m wide strip product.

Ladle 17 is of entirely conventional construction and is supported via a yoke 45 on an overhead crane whence it can be brought into position from a hot metal receiving station. The ladle is fitted with a stopper rod 46 actuable by a servo cylinder to allow molten metal to flow from the ladle through an outlet nozzle 47 and refractory shroud 48 into distributor 18.

Distributor 18 is formed as a wide dish made of a refractory material such as high alumina castable with a sacrificial lining. One side of the distributor receives molten metal from the ladle and is provided with the aforesaid overflow 24. The other side of the distributor is provided with a series of longitudinally spaced metal outlet openings 52. The lower part of the distributor carries mounting brackets 53 for mounting the distributor onto the roll carriage frame 31 and provided with apertures to receive indexing pegs 54 on the carriage frame so as accurately to locate the distributor.

Delivery nozzle 19 is formed in two identical half segments which are made of a refractory material such as alumina graphite are held end to end to form the complete nozzle. Figures 5 to 11 illustrate the construction of the nozzle segments which are supported on the roll carriage frame by a mounting bracket 60, the upper parts of the nozzle segments being formed with outwardly projecting side flanges 55 which locate on that mounting bracket.

Each nozzle half segment is of generally trough formation so that the nozzle 19 defines an upwardly opening inlet trough 61 to receive molten metal flowing downwardly from the openings 52 of the distributor. Trough 61 is formed between nozzle side walls 62 and end walls 70 and may be considered to be transversely partitioned between its ends by the two flat end walls 80 of the nozzle segments which are brought together in the completed nozzle. The bottom of the trough is closed by a horizontal bottom floor 63 which meets the trough side walls 62 at chamfered bottom corners 81. The nozzle is provided at these bottom corners with a series of side openings in the form of longitudinally spaced elongate slots 64 arranged at regular longitudinal spacing along the nozzle. Slots 64 are positioned to provide for egress of molten metal from the trough at the level of the trough floor 63. The trough floor is provided adjacent the slots with recesses 83 which slope outwardly and downward-

ly from the centre of the floor toward the slots and the slots continue as extensions of the recesses 83 to slot outlets 84 disposed in the chamfered bottom corners 80 of the nozzle beneath the level of the upper floor surface 85.

The outer ends of the nozzle segments are provided with triple point pouring end formations denoted generally as 87 extending outwardly beyond the nozzle end wall 70. Each end wall formation 87 defines a small open topped reservoir 88 to receive molten metal from the distributor, this reservoir being separated from the main trough of the nozzle by the end wall 70. The upper end 89 of end wall 70 is lower than the upper edges of the trough and the outer parts of the reservoir 88 and can serve as a weir to allow back flow of molten metal into the main nozzle trough from the reservoir 88 if the reservoir is over filled, as will be more fully explained below.

Reservoir 88 is shaped as a shallow dish having a flat floor 91, inclined inner and side faces 92, 93 and a curved upright outer face 94. A pair of triple point pouring passages 95 extend laterally outwardly from this reservoir just above the level of the floor 91 to connect with triple point pouring outlets 96 in the undersides of the nozzle end formations 87, the outlets 96 being angled downwardly and inwardly to deliver molten metal into the triple point regions of the casting pool.

Molten metal falls from the outlet openings 52 of the distributor in a series of free-falling vertical streams 65 into the bottom part of the nozzle trough 61. Molten metal flows from this reservoir out through the side openings 64 to form a casting pool 68 supported above the nip 69 between the casting rolls 16. The casting pool is confined at the ends of rolls 16 by a pair of side closure plates 56 which are held against the ends 57 of the rolls. Side closure plates 56 are made of strong refractory material, for example boron nitride. They are mounted in plate holders 82 which are movable by actuation of a pair of hydraulic cylinder units 83 to bring the side plates into engagement with the ends of the casting rolls to form end closures for the casting pool of molten metal.

In the casting operation the flow of metal is controlled to maintain the casting pool at a level such that the lower end of the delivery nozzle 19 is submerged in the casting pool and the two series of horizontally spaced side openings 64 of the delivery nozzle are disposed immediately beneath the surface of the casting pool. The molten metal flows through the openings 64 in two laterally outwardly directed jet streams in the general vicinity of the casting pool surface so as to impinge on the cooling surfaces of the rolls in the immediate vicinity of the pool surface. This maximises the temperature of the molten metal delivered to the meniscus regions of the pool and it has been found that this significantly reduces the formation of cracks and meniscus marks on the melting strip surface.

Molten metal is caused to flow from the extreme bottom part of the nozzle trough 61 through the nozzle side openings 64 generally at the level of the floor of the

trough. The metal enters the casting pool in mutually oppositely directed jet streams immediately below the surface of the pool to impinge on the casting roll surfaces in the meniscus regions of the pool. The outlet slots 64 are sized to provide a flow rate which allows the metal to flow directly into the pool without accumulating any substantial head of metal within the nozzle trough. Accordingly the falling molten metal streams 65 impinge directly onto the upper surface 85 of the nozzle floor 63 to fan outwardly across the floor and across the floor recesses 83 into the slot outlets 64. To enhance this conversion of kinetic energy to outward fanning movement of the metal the outlet openings 52 of the distributor are staggered longitudinally of the nozzle with respect to the nozzle side openings 64 so that the falling streams 65 impinge on the nozzle floor at locations between successive pairs of side openings 64. Accordingly they impinge on the flat regions of the floor 97 disposed between the recesses 83. It has been found that the system can be operated to establish a casting pool which rises to a level only just above the bottom of the delivery nozzle so that the casting pool surface is only just above the floor of the nozzle trough and at the same level as the metal within the trough. Under these conditions it is possible to obtain very stable pool conditions and if the outlet slots are angled downwardly to a sufficient degree it is possible to obtain a quiescent pool surface. By varying the outward and downward inclination of the side openings along the length of the nozzle it is possible to create quiescent regions at which the pool level can be monitored by cameras or other sensors while other parts of the pool are more turbulent to enhance heat transfer at the meniscus regions.

It is also possible by varying the inclination of the nozzle side outlets to produce more turbulence in the central regions of the nozzle compared with regions at the two ends of the nozzle which has the effect of driving slag on the pool surface to the ends of the pool so that it deposits preferentially at the edges of the strip which will be trimmed off in a subsequent side trimming operation. For this purpose the outward and downward inclination of the side openings may vary progressively from shallow angles in the central region of the nozzle to steeper angles toward the ends of the nozzle. This arrangement is most suitable for use with nozzles provided with triple point pouring end formations since the triple point pouring keeps slag away from the side dam plates.

It is important to note that nozzle side slots 64 are provided at the inner ends of the two nozzle sections. This ensures adequate delivery of molten metal to the pool in the vicinity of the central partition in the nozzle and avoids the formation of skulls in this region of the pool.

The triple point pouring reservoirs 88 receive molten metal from the two outermost streams 65 falling from the distributor 18. The alignment of the two outermost holes 52 in the distributor is such that each reservoir 88

receives a single stream impinging on the flat floor 91 immediately outside the sloping side face 92. The impingement of the molten metal on floor 88 causes the metal to fan outwardly across the floor and outwardly through the triple point pouring passages 95 to the outlets 96 which produce downwardly and inwardly inclined jets of hot metal directed across the faces of the side dams and along the edges of the casting rolls toward the nip. Triple point pouring proceeds with only a shallow and wide pool of molten metal within each of the troughs 88, the height of this pool being limited by the height of the upper end 89 of the wall 70. When reservoir 88 is filled molten metal can flow back over the wall end 89 into the main nozzle trough so that the wall end serves as a weir to control the depth of the metal pool in the triple point pouring supply reservoir 88. The depth of the pool is more than sufficient to supply the triple point pouring passages so as to maintain flow at a constant head whereby to achieve a very even flow of hot metal through the triple point pouring passages. This control flow is most important to proper formation of the edge parts of the strip. Excessive flow through the triple point passages can lead to bulging in the edges of the strip whereas too little flow will produce skulls and "snake egg" defects in the strip.

The undersides 98 of the triple point pouring formations 87 are raised above the surface of the casting pool so as to avoid cooling of the pool surface at the triple point region. Moreover, the undersides 98 are outwardly and upwardly inclined. This is desirable in order to prevent an accumulation of slag or other contaminants from jamming beneath the ends of the nozzle. Such jamming can result in blockage of gas and fumes escaping from the casting pool and the risk of explosion.

The illustrated apparatus has been advanced by way of example only and the invention is not limited to the details of that apparatus. In particular it is not essential in the present invention that the nozzle trough be provided with side openings of the kind shown in the illustrated apparatus, although that is the presently preferred form of nozzle. It would alternatively be possible to adopt side openings in the manner described in Australian Patent Application 60773/96 or one or more bottom openings in the nozzle trough. The invention may in fact be applied to any metal delivery nozzle which has an open topped main delivery trough into which molten metal from triple point pouring reservoirs can be caused to overflow.

Claims

1. Apparatus for casting metal strip, comprising a pair of parallel casting rolls (16) forming a nip (69) between them, an elongate metal delivery nozzle (19) disposed above and extending along the nip between the casting rolls for delivery of molten metal into the nip whereby to form a casting pool (68) sup-

ported above the nip (69), a distributor (18) disposed above the delivery nozzle for supply of molten metal to the delivery nozzle in discrete streams (65), and a pair of pool confinement plates (56) at the ends of the nip, wherein the metal delivery nozzle (19) comprises an upwardly opening elongate trough (61) extending longitudinally of the nip (69) to receive discrete streams (65) of molten metal from the distributor and trough outlet means (64) to deliver molten metal from the trough into the casting pool (68) characterised in that, the nozzle has outer end formations (87) defining reservoirs (88) for molten metal at the two ends of the nozzle which each receive discrete streams (65) of metal from the distributor and flow passages (95) extending from the reservoirs to direct molten metal from the reservoirs in streams directed downwardly across the pool confining end closures (56), and each of said reservoirs (88) is separated from the nozzle trough (61) by separator means establishing a maximum depth of accumulated molten metal in the reservoir (88) beyond which molten metal can overflow from the reservoir (8) into the nozzle trough (61).

2. Apparatus as claimed in claim 1, further characterised in that the separator means is in the form of an upstanding wall (70) constituting an outer end wall of the trough and an inner end wall of the reservoir.

3. Apparatus as claimed in claim 2, further characterised in that said upstanding wall (70) functions as a weir for molten metal in the reservoir such that metal can flow over its upper edge (89) into the trough when the reservoir (88) is full.

4. Apparatus as claimed in any one of claims 1 to 3, further characterised in that, wherein each reservoir (88) is in the form of an open topped dish which is shallow relative to the trough (61) and is elevated above the floor (63) of the trough.

5. Apparatus as claimed in any one of claims 1 to 4 further characterised in that the undersides (98) of the nozzle end formations (87) are raised above the bottom end of the nozzle so as in use of the apparatus to be raised clear of the casting pool (68).

6. Apparatus as claimed in claim 5, further characterised in that the undersides (98) of the nozzle end formations (87) slope upwardly and outwardly of the nozzle ends.

7. Apparatus as claimed in any one of claims 1 to 6 further characterised in that the nozzle receives a plurality of discrete streams (65) of molten metal from the distributor throughout the length of the nozzle.

8. Apparatus as claimed in any one of claims 1 to 7, further characterised in that the volume of the discrete streams (65) received by the reservoirs (88) of the outer end formations (87) is larger than the individual discrete streams (65) received by said upwardly opening trough (61). 5
9. A refractory nozzle for delivery of molten metal to a casting pool of a twin roll caster, said nozzle comprising an elongate open topped trough (61) to receive molten metal and trough outlet means (64) for delivery of molten metal from the trough to the casting pool, which nozzle is provided with end formations (87) defining reservoirs (88) to receive molten metal at the two ends of the nozzle and flow passages (95) extending from the reservoirs to direct molten metal from the reservoirs in streams directed downwardly from the nozzle end formations (87), wherein each of said reservoirs (88) is separated from the nozzle trough (61) by separator means establishing a maximum depth of accumulated molten metal in the reservoir beyond which molten metal can overflow from the reservoir into the nozzle trough. 10
15
20
25
10. A refractory nozzle as claimed in claim 10, further characterised in that the separator means is in the form of an upstanding wall (70) constituting an outer end wall of the trough (61) and an inner end wall of the reservoir (88). 30
11. A refractory nozzle as claimed in claim 10, further characterised in that said upstanding wall (70) has an upper end (89) which is lower than the upper edge of the trough (61) and the outer parts of the reservoir (88) so that it can serve as a weir over which metal can flow into the trough (61) from the reservoir (88) when the reservoir is full. 35
12. A refractory nozzle as claimed in any one of claims 9 to 11, further characterised in that each reservoir (88) is in the form of an open topped dish which is shallow relative to the trough (61) and is elevated above the floor (63) of the trough. 40
45
13. A refractory nozzle as claimed in any one of claims 9 to 12, further characterised in that the undersides (98) of the nozzle end formations (87) are raised above the bottom end of the nozzle. 50
14. A refractory nozzle as claimed in claim 13, further characterised in that the undersides (98) of the nozzle end formations (87) slope upwardly and outwardly of the nozzle ends. 55

Fig. 3.
